

The Water Cycle

The water cycle is something that goes around and around. Why does it go around and around?

Well it goes around and around because it rises in the sun. This is called evaporation.

Then it goes into the cloud because it cools down and condenses.

The cloud goes over the land and rains. This is called precipitation. And then it goes to around to the river and into the ocean and then it starts again.

So as you can see the water cycle is something that goes around and around and never stops and never starts but if we don't look after it, it wont work.

The Water Cycle

The water cycle is something that tells you about water. The water cycle is something that goes around and around and never stops.

Evaporation is something that is like water vapour. It rises because the sun heats it up in the sky.

Condensation is when it rises and it condenses into a cloud. When it cools down it condenses.

Precipitation is rain. It fills up in a cloud and then it rains again then it goes down a river and starts again.

So as you can see water never stops and never ends, it's a never ending cycle. Now you know how the water cycle works so you know how important it is to look after it.

How the Water Cycle Works

Have you ever heard of the water cycle? The water cycle is something that goes around and around.

When water evaporates it is called water vapour and then it turns into a cloud because it cools down and then it rains. This is called precipitation and it goes into the ocean.

So now you know, if it rains, do not be angry about it because the water is special.

The Water Cycle

The water cycle is a very important part of the world.

When it is hot the water evaporates. When it hits your hand it turns into moisture.

Condensation is cold water vapour. Cold water vapour is a cloud.

Precipitation is a fancy word for rain. The rain goes in a river and then into the ocean. Then the cycle starts again.

As you can see the water cycle is a very important part of the earth because water is very good for you.

The Water Cycle

The water cycle tells you about water and it never ends.

The water evaporates from the ocean because water vapour goes up to the sun to heat the water.

The water vapour cools down and rains and turns in to a cloud and condenses.

Then it rains. This is called precipitation.

The water cycle is special.
